Chapter 1

Random Walks and First Step Analysis

Chapter 2

First Martingale Steps

Exercise 2.1 The roots of the equation qualify for the x

$$E(x_1^X) = \frac{0.52}{x} + 0.45x + 0.03x^2 = 1.$$

Form

$$\frac{0.52}{x} + 0.45x + 0.03x^2 - 1 = \frac{x-1}{x}(0.03x^2 + 0.48x - 0.52)$$

we have the following three values.

$$x = 1, \frac{-0.24 \pm \sqrt{0.24^2 + 0.03 \times 0.24}}{0.03} = 1, 1.01850, -17.0185.$$

We pick $x = 1.01850$ since the change under high powers are reasonable. If we let τ be the first time Gambler's wealth is either 100, 101 or -100, we have the equation from the Martingale property,

$$1 = E(M_\tau) = x^{100}P(S_\tau = 100) + x^{101}P(S_\tau = 101) + x^{-100}P(S_\tau = -100).$$

Letting $p = P(S_\tau = 100) + P(S_\tau = 101)$ and using the fact that $x > 1$,

$$\begin{aligned} x^{100}p + x^{-100}(1-p) &< 1 < x^{101}p + x^{-100}(1-p) \\ \frac{1 - x^{-100}}{x^{101} - x^{-100}} &< p < \frac{1 - x^{-100}}{x^{100} - x^{-100}} \Rightarrow 0.13531 < x < 0.13788. \end{aligned}$$

Exercise 2.4 From the hint, let us define

$$A_{n+1} = A_n + E[(M_{n+1} - M_n)^2 | \mathcal{F}_n]$$

and prove the three required properties:

(i) N_n is a martingale.

$$\begin{aligned} E[N_{n+1} | \mathcal{F}_n] &= E[M_{n+1}^2 - A_{n+1} | \mathcal{F}_n] \\ &= E[2M_{n+1}M_n - M_n^2 - A_n | \mathcal{F}_n] \\ &= 2E[M_{n+1} | \mathcal{F}_n] M_n - M_n^2 - A_n \\ &= M_n^2 - A_n = N_n. \end{aligned}$$

(ii) $A_{n+1} \geq A_n$ is trivial.

(iii) A_n is non-anticipating because it is defined via the expectation under \mathcal{F}_n .

Chapter 3

Brownian Motion

Exercise 3.1 (Brownian Bridge) (a) This problem is based on a series representation of Brownian motion ([WIKIPEDIA](#)). See p.286 of **SCFA** also.

$$B_t = tZ_0 + \sum_{k=1}^{\infty} \sqrt{2} Z_k \frac{\sin \pi k t}{\pi k}$$

for independent standard normal random variables, $\{Z_{k \geq 0}\}$. (But I think the author somehow dropped this in the current version of the textbook.) So, $\Delta_0(t) = t$ and $\lambda_0 = 1$. Because $B_1 = Z_0$ (from $\Delta_{k \geq 1}(1) = 0$), the first term can be expressed as $\lambda_0 Z_0 \Delta_0(t) = t B_1$. Therefore,

$$U_t = B_t - tB_1$$

(b)

$$\begin{aligned} \text{Cov}(U_s, U_t) &= E\left((B_s - sB_1)(B_t - tB_1)\right) = E\left(B_s B_t - sB_1 B_t - tB_s B_1 + stB_1^2\right) \\ &= \min(s, t) - s \min(1, t) - t \min(s, 1) + st = s(1 - t) \end{aligned}$$

(c) We need to find any set of functions, $g(\cdot)$ and $h(\cdot)$, such that

$$\text{Cov}(X_s, X_t) = g(s)g(t) \min(h(s), h(t)) = s(1 - t) \quad \text{for } s \leq t.$$

If we narrow down the search by assuming $h(\cdot)$ is monotonically increasing,

$$\text{Cov}(X_s, X_t) = g(s)g(t)h(s) = s(1 - t),$$

so we get

$$g(t) = 1 - t, \quad h(s) = \frac{s}{1 - s},$$

where $h(s)$ is indeed an increasing function. Therefore we obtained a representation of Brownian bridge,

$$X_t = (1 - t)B_{\frac{t}{1-t}}$$

Since U_{1-t} is also a Brownian bridge due to the symmetry,

$$X_{1-t} = tB_{\frac{1-t}{t}}, \quad \left(g(t) = t, \quad h(t) = \frac{1-t}{t}\right)$$

is also a valid solution.

(d) We use the inequality $s/(1+s) \leq t/(1+t)$ if $0 \leq s \leq t$.

$$\begin{aligned} \text{Cov}(Y_s, Y_t) &= \text{Cov}\left((1+s)U_{\frac{s}{1+s}}(1+t)U_{\frac{t}{1+t}}\right) = (1+s)(1+t)\text{Cov}\left(U_{\frac{s}{1+s}}, U_{\frac{t}{1+t}}\right) \\ &= (1+s)(1+t) \frac{s}{1+s} \left(1 - \frac{t}{1+t}\right) = s = \min(s, t). \end{aligned}$$

Exercise 3.2 (Cautionary Tale) Suppose X is a standard normal, consider an independent U such that $P(U = 1) = 1/2 = P(U = -1)$, and set $Y = UX$. Then, Y is also a standard normal as X and $-X$ are also standard normal.

In order to show X and Y are not independent, we need to show

$$\text{Prob}(I_X \& J_Y) \neq \text{Prob}(I_X)\text{Prob}(J_Y)$$

for some event I_X and I_Y regarding X and Y respectively.

For any $h > 0$,

$$\begin{aligned} \text{Prob}(X > h \& Y > h) &= \frac{1}{2}\text{Prob}(X > h \& X > h \mid U = 1) \\ &\quad + \frac{1}{2}\text{Prob}(X > h \& -X > h \mid U = -1) \\ &= \frac{1}{2}(1 - \Phi(h)) + 0. \end{aligned}$$

However,

$$\text{Prob}(X > h)\text{Prob}(Y > h) = (1 - \Phi(h))(1 - \Phi(h))$$

is not same as the previous value. Therefore

Exercise 3.3 (Multivariate Gaussians)

(a) Let us work on each components of the vectors and matrices; $V = (v_i)$, $\mu = (\mu_i)$, $A = (a_{ij})$ and $\Sigma = (\sigma_{ij})$.

$$\begin{aligned} E((AV)_i) &= E\left(\sum_j a_{ij}V_j\right) = \sum_j a_{ij}E(V_j) = \sum_j a_{ij}\mu_j = (A\mu)_i \\ E((AV)) &= A\mu \end{aligned}$$

$$\begin{aligned} \text{Cov}((AV)_i, (AV)_j) &= \text{Cov}\left(\sum_l a_{il}V_l, \sum_m a_{jm}V_m\right) = \sum_{l,m} a_{il}\text{Cov}(V_l, V_m)a_{jm} \\ &= \sum_{l,m} a_{il}\sigma_{lm}a_{jm} = (A\Sigma A^T)_{ij} \end{aligned}$$

Therefore,

$$\text{Cov}(AV, AV) = A\Sigma A^T.$$

(b)

$$E(X \pm Y) = E(X) \pm E(Y) = 0 \pm 0 = 0$$

$$\text{Var}(X \pm Y) = \text{Var}(X) + \text{Var}(Y) \pm 2\text{Cov}(X, Y) = 1 + 1 + 0 = 2$$

$$\text{Cov}(X + Y, X - Y) = \text{Var}(X) - \text{Var}(Y) = 1 - 1 = 0$$

(c) When $\text{Cov}(X, Y) = 0$, the covariance matrix Σ is given as

$$\Sigma = \begin{pmatrix} \sigma_{11} & 0 \\ 0 & \sigma_{22} \end{pmatrix}, \quad \Sigma^{-1} = \begin{pmatrix} 1/\sigma_{11} & 0 \\ 0 & 1/\sigma_{22} \end{pmatrix}, \quad \det \Sigma = \sigma_{11} \sigma_{22}$$

The joint density function can be factored to the product of the single variable density function,

$$\begin{aligned} f(x, y) &= \frac{1}{2\pi\sqrt{\sigma_{11}\sigma_{22}}} \exp\left(-\frac{(x-\mu_X)^2}{2\sigma_{11}} - \frac{(y-\mu_Y)^2}{2\sigma_{22}}\right) \\ &= \frac{1}{2\pi\sqrt{\sigma_{11}}} \exp\left(-\frac{(x-\mu_X)^2}{2\sigma_{11}}\right) \frac{1}{2\pi\sqrt{\sigma_{22}}} \exp\left(-\frac{(y-\mu_Y)^2}{2\sigma_{22}}\right) = f(x)f(y). \end{aligned}$$

Therefore X and Y are independent.

(d) We first find the matrix A such that, for the independent standard normal variables W and Z ,

$$\begin{pmatrix} X - \mu_X \\ Y - \mu_Y \end{pmatrix} = A \begin{pmatrix} W \\ Z \end{pmatrix}$$

has the given covariance matrix

$$\begin{pmatrix} \sigma_{XX} & \sigma_{XY} \\ \sigma_{XY} & \sigma_{YY} \end{pmatrix} = A I A^T = A A^T.$$

One of the solution from Cholesky decomposition is

$$A = \begin{pmatrix} \sqrt{\sigma_{XX}} & 0 \\ \sigma_{XY}/\sqrt{\sigma_{XX}} & \sqrt{\sigma_{YY} - \sigma_{XY}^2/\sigma_{XX}} \end{pmatrix}.$$

Conditional on that $X = x$,

$$Y = \mu_Y + \frac{\sigma_{XY}}{\sqrt{\sigma_{XX}}} \frac{x - \mu_X}{\sqrt{\sigma_{XX}}} + Z \sqrt{\sigma_{YY} - \sigma_{XY}^2/\sigma_{XX}}.$$

Therefore

$$\begin{aligned} E(Y|X = x) &= \frac{\sigma_{XY}}{\sigma_{XX}}(x - \mu_X) = \frac{\text{Cov}(X, Y)}{\text{Var}(X)}(x - \mu_X) \\ \text{Var}(Y|X = x) &= \sigma_{YY} - \frac{\sigma_{XY}^2}{\sigma_{XX}} = \text{Var}(Y) - \frac{\text{Cov}^2(X, Y)}{\text{Var}(X)} \end{aligned}$$

Exercise 3.4 (Auxiliary Functions and Moments)

$$E(e^{tz}) = \int_{-\infty}^{\infty} e^{tz} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \int_{-\infty}^{\infty} e^{t^2/2} \frac{1}{\sqrt{2\pi}} e^{-(z-t)^2/2} dz = e^{t^2/2}$$

If M_n is the n -th moment,

$$E(e^{tz}) = \sum_{k=0}^{\infty} M_k \frac{t^k}{k!} = 1 + \frac{t^2}{2} + \frac{1}{2!} \left(\frac{t^2}{2}\right)^2 + \frac{1}{3!} \left(\frac{t^2}{2}\right)^3 + \dots$$

By matching the coefficients, we get

$$\begin{aligned} M_0 &= 1 \\ M_1 &= M_3 (= M_{2k-1}) = 0 \\ M_2 &= 1 \\ M_4 &= 4!/(2! 2^2) = 3 \\ M_6 &= 6!/(3! 2^3) = 15. \end{aligned}$$

For $t > 0$,

$$E(e^{tz^4}) = \int_{-\infty}^{\infty} e^{tz^4} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz \rightarrow \infty,$$

so the MGF of Z^4 does not exist.

Chapter 4

Martingales: The next steps

Exercise 4.6 The stopped process is a martingale. By the symmetry, $P(B_\tau = A) = P(B_\tau = -A) = 0.5$.

$$1 = E(X_\tau) = \frac{1}{2}e^{\alpha A}E(e^{-\alpha^2\tau/2}) + \frac{1}{2}e^{-\alpha A}E(e^{-\alpha^2\tau/2}).$$

Therefore, we have

$$E(e^{-\alpha^2\tau/2}) = \frac{1}{\cosh(\alpha A)}$$

or

$$\phi(\lambda) = E(e^{-\lambda\tau}) = \frac{1}{\cosh(A\sqrt{2\lambda})}.$$

In order to calculate $E(\tau^2)$, we need to obtain the x^4 term in the expansion of $1/\cosh(x)$ given that $\sqrt{\lambda}$ appears in the expression. From the expansion, $\cosh x \sim 1 + x^2/2! + x^4/4! + \dots$,

$$\frac{1}{\cosh x} \sim \frac{1}{1 + (x^2/2! + x^4/4! + \dots)} = 1 - \left(\frac{x^2}{2!} + \frac{x^4}{4!} + \dots\right) + \left(\frac{x^2}{2!} + \dots\right)^2 = 1 - \frac{x^2}{2} + \frac{5}{24}x^4 + \dots.$$

Finally we get

$$E(\tau^2) = 2\frac{5}{24}(A\sqrt{2\lambda})^4|_{\lambda=1} = \frac{5}{3}A^4$$

For the non-symmetric case ($A \neq B$), we can not use $P(B_\tau = A) = P(B_\tau = -B) = 0.5$ anymore.

Chapter 5

Richness of Paths

Extra Problem on Ch. 5 Derive the probability results on the running maximum and the first hitting time to the BM with the volatility σ . Using the scaling, $\sigma B_t = B_{\sigma^2 t}$, you are going to replace t with $\sigma^2 t$.

For the CDF (on both time and space) and the PDF on space, the simple replacement works.

$$P(\sigma B_t^* < x) = P(\tau_x > t) = 2\Phi(x/\sigma\sqrt{t}) - 1.$$

$$f_{\sigma B_t^*}(x) = \frac{2}{\sigma\sqrt{t}} \phi\left(\frac{x}{\sigma\sqrt{t}}\right)$$

For the PDF on time, however, we need to consider the normalization because the time is scaled. The original PDF $f_{\tau_x}(t)$ satisfies $\int_0^\infty f_{\tau_x}(t) dt = 1$. After the scaling,

$$\int_0^\infty f_{\tau_x}(\sigma^2 t) dt = \frac{1}{\sigma^2},$$

so the new PDF should be

$$\sigma^2 f_{\tau_x}(\sigma^2 t) = \frac{x}{\sigma t^{3/2}} \phi\left(\frac{x}{\sigma\sqrt{t}}\right).$$

Chapter 6

Itô Integration

Exercise 6.1 The mean of the two expressions are zero.

$$\text{Var} \left(\int_0^t |B_s|^{\frac{1}{2}} dB_s \right) = E \left(\int_0^t |B_s| ds \right) = \int_0^t E(|B_s|) ds = \int_0^t \sqrt{\frac{2s}{\pi}} ds = \frac{2}{3} \sqrt{\frac{2}{\pi}} t^{\frac{3}{2}}$$

$$\begin{aligned} \text{Var} \left(\int_0^t (B_s + s)^2 dB_s \right) &= E \left(\int_0^t (B_s + s)^4 ds \right) = \int_0^t E(B_s^4 + 4sB_s^3 + 6s^2B_s^2 + 4s^3B_s + s^4) ds \\ &= \int_0^t (3s^2 + 0 + 6s^2 \cdot s + 0 + s^4) ds = \frac{1}{5}t^5 + \frac{3}{2}t^4 + t^3 \end{aligned}$$

Exercise 6.2 For I_1 ,

$$E(I_1) = \int_0^t E(B_s) ds = \int_0^t 0 ds = 0.$$

Using Itô's lemma applied to sB_s , $d(sB_s) = s dB_s + B_s ds$, we can express I_1 as

$$I_1 = tB_t - \int_0^t s dB_s = t \int_0^t dB_s - \int_0^t s dB_s = \int_0^t (t - s) dB_s,$$

where we used a trick of $B_t = \int_0^t dB_s$ in order to make the expression suitable for Ito's isometry. We get

$$\text{Var}(I_1) = \int_0^t (t - s)^2 ds = \frac{1}{3}t^3$$

For I_2 ,

$$E(I_2) = \int_0^t E(B_s^2) ds = \int_0^t s ds = \frac{t^2}{2}.$$

Using Itô's lemma applied to sB_s^2 , $d(sB_s^2) = B_s^2 ds + 2sB_s dB_s + s ds$, we can express I_2 as

$$I_2 = tB_t^2 - 2 \int_0^t sB_s dB_s - \frac{t^2}{2}.$$

We apply a similar trick, $d(B_s^2) = 2B_s dB_s + ds$, to replace B_t^2 with a more suitable expression for Itô's isometry,

$$I_2 = t \left(2 \int_0^t B_s dB_s + t \right) - 2 \int_0^t sB_s dB_s - \frac{t^2}{2} = 2 \int_0^t (t - s) B_s dB_s + \frac{t^2}{2},$$

where we can reconfirm that $E(I_2) = t^2/2$. Finally,

$$\text{Var}(I_2) = E\left(\left(I_2 - \frac{t^2}{2}\right)^2\right) = 4 \int_0^t E\left((t-s)^2 B_s^2\right) ds = 4 \int_0^t (t-s)^2 s ds = 4 \cdot \frac{t^4}{12} = \frac{t^4}{3}$$

Exercise 6.3 At any time s , X_s and B_s has the same distribution, normal distribution with mean 0 and variance s , so $E(f(B_s)) = E(f(X_s))$ and

$$E(U_t) = \int_0^t E(f(B_s)) ds = \int_0^t E(f(X_s)) ds = E(V_t)$$

For variance, simply let $f(x) = x$. Using that $V_t = \int_0^t \sqrt{s} Z ds = \frac{2}{3} t^{\frac{3}{2}} Z$,

$$\text{Var}(V_t) = \frac{4}{9} t^3.$$

According to **Exercise 6.2**, however,

$$\text{Var}(U_t) = \frac{1}{3} t^3 \neq \text{Var}(V_t).$$

Chapter 7

Localization and Itô's integral

Exercise 7.1

$$\tau_t = \text{Var}(Y_t) = \text{Var}(X_t) = \int_0^t e^{2s} ds = \frac{1}{2}(e^{2t} - 1)$$

$$E(X_t^2) = \int_0^t e^{2s} ds = \frac{1}{2}(e^{2t} - 1), \quad E(Y_t^2) = \tau_t = \frac{1}{2}(e^{2t} - 1)$$

$$E(X_t^4) = E(Y_t^2 = B_{\tau_t}^4) = 3\tau_t^2 = \frac{3}{4}(e^{2t} - 1)^2$$

Note the difference between this problem and **Corollary 7.1** (Brownian motion time change). Given B_t is a standard BM,

$$X_t = \int_0^t f(s) dB_s, \quad \text{and} \quad \tau(t) = v = \text{Var}(X_t) = \int_0^t f^2(s) ds,$$

this exercise problem is effectively stating that X_t and $B_{\tau(t)}$ are same processes. Whereas, the Corollary 7.1 states that $X_{\tau^{-1}(v)}$ and B_v are same processes where $\tau^{-1}(\cdot)$ is the inverse function of $\tau(\cdot)$, i.e., $t = \tau^{-1}(v)$. Although they look different in forms, the intuitions behind them are same in that the variance of X_t can be used as a new *time scale* of a standard BM.

Chapter 8

Itô's Formula

Exercise 8.2 (The notation $h \in C^1(\mathbb{R}^+)$ means that the function $h(s)$ is differentiable for $s > 0$.)
From the SDE of $h(t)B_t$,

$$d(h(t)B_t) = h(t)dB_t + h'(t)B_t dt$$

we get

$$\int_0^t h(s)dB_s = h(t)B_t - \int_0^t h'(s)B_s ds.$$

Using that $B_T = \int_0^T dB_t$, we also get another useful result:

$$\int_0^T h'(s)B_s ds = h(T)B_T - \int_0^T h(t)dB_t = \int_0^T (h(T) - h(t))dB_t$$

Exercise 8.4 (The sub-problem (b) is understood better after **HW 3-2** is solved.)

(a) If $f(t, x) = \phi(t)\psi(x)$, the condition $f_t = -\frac{1}{2}f_{xx}$ yields to

$$-2\frac{\phi_t(t)}{\phi(t)} = \frac{\psi_{xx}(x)}{\psi(x)} = \lambda,$$

where λ is a constant. If $\lambda > 0$ ($\lambda = \alpha^2$ for some α), we get the GBM solution,

$$\phi(t) = \phi(0)e^{-\alpha^2 t/2} \quad \text{and} \quad \psi(x) = Ae^{\alpha x} + Be^{-\alpha x} \text{ for constants } A, B$$

$$M_t = (Ae^{\alpha B_t} + Be^{-\alpha B_t})e^{-\alpha^2 t/2}$$

If $\lambda < 0$ ($\lambda = -\alpha^2$ for some α), we get

$$M_t = (A \cos(\alpha B_t) + B \sin(-\alpha B_t))e^{\alpha^2 t/2}$$

If $\lambda = 0$, we get $\phi(t) = \phi(0)$ and $\psi(x) = Ax + B$, therefore we have

$$M_t = AB_t + B.$$

(b)

$$\begin{aligned} M_t &= 1 + (\alpha B_t - \alpha^2 t/2) + \frac{1}{2}(\alpha B_t - \alpha^2 t/2)^2 + \frac{1}{6}(\alpha B_t - \alpha^2 t/2)^3 + \frac{1}{24}(\alpha B_t - \alpha^2 t/2)^4 + \dots \\ &= 1 + (B_t)\alpha + \frac{1}{2}(B_t^2 - t)\alpha^2 + \frac{1}{6}(B_t^3 - 3tB_t)\alpha^3 + \frac{1}{24}(B_t^4 - 6tB_t^2 + 3t^2)\alpha^4 + \dots \end{aligned}$$

We get the first five martingales as below:

$$H_0(t, B_t) = 1$$

$$H_1(t, B_t) = B_t$$

$$H_2(t, B_t) = \frac{1}{2}(B_t^2 - t)$$

$$H_3(t, B_t) = \frac{1}{6}(B_t^3 - 3tB_t)$$

$$H_4(t, B_t) = \frac{1}{24}(B_t^4 - 6tB_t^2 + 3t^2).$$

Chapter 9

Stochastic Differential Equations

Exercise 9.1 This is slightly modified from the OU process with the extra βdt term. We use the same initial guess, $e^{\alpha t} X_t$, for the OU process.

$$\begin{aligned} d(e^{\alpha t} X_t) &= \alpha e^{\alpha t} X_t dt + e^{\alpha t} dX_t + \frac{1}{2} 0 (dX_t)^2 \\ &= e^{\alpha t} (\alpha X_t dt - \alpha X_t dt + \beta dt) + \sigma e^{\alpha t} dB_t = -\beta e^{\alpha t} dt + \sigma e^{\alpha t} dB_t. \end{aligned}$$

Therefore, we get

$$\begin{aligned} e^{\alpha t} X_t - X_0 &= \beta(e^{\alpha t} - 1) + \sigma \int_0^t e^{\alpha s} dB_s \\ X_t &= e^{-\alpha t} X_0 + \beta(1 - e^{-\alpha t}) + \sigma e^{-\alpha t} \int_0^t e^{\alpha s} dB_s. \end{aligned}$$

Exercise 9.2 We first guess from the traditional calculus. We let $x = X_t$ and solve

$$e^{-t^2/2} dx = t x e^{-t^2/2} dt \quad \Rightarrow \quad \frac{dx}{x} = -t dt$$

Luckily we can solve this to have $x = C e^{t^2/2}$ or $e^{-t^2/2} x = C$ for some constant C , so we stochastically differentiate $e^{-t^2/2} X_t$ to get

$$d(e^{-t^2/2} X_t) = -t e^{-t^2/2} X_t dt + e^{-t^2/2} (t X_t dt + e^{t^2/2} dB_t) = dB_t.$$

We can solve the SDE as

$$e^{-t^2/2} X_t - X_0 = B_t \quad \Rightarrow \quad X_t = e^{t^2/2} (B_t + X_0).$$

Exercise 9.3 The guess from the traditional calculus is

$$\frac{dx}{x} = \frac{-2}{1-t} dt \quad \Rightarrow \quad x = C(1-t)^2.$$

Therefore we start by differentiating $(1-t)^{-2} X_t$:

$$d\left(\frac{X_t}{(1-t)^2}\right) = 2 \frac{X_t}{(1-t)^3} dt + \frac{1}{(1-t)^2} \left(-2 \frac{X_t}{1-t} dt + \sqrt{2t(1-t)} dB_t\right) = \frac{\sqrt{2t}}{(1-t)^{3/2}} dB_t$$

and finally solve the SDE as

$$X_t = (1-t)^2 \int_0^t \frac{\sqrt{2u}}{(1-u)^{3/2}} dB_u.$$

Since the integrand $\sqrt{2u}(1-u)^{-3/2}$ depends only on the time variable u , X_t is a Gaussian process with the variance

$$\begin{aligned}\text{Var}(X_t) &= (1-t)^4 \int_0^t \frac{2u}{(1-u)^3} du = (1-t)^4 \int_{1-t}^1 \frac{2(1-u')}{u'^3} du' \quad (u' = 1-u) \\ &= (1-t)^4 \left(1 - \frac{2}{1-t} + \frac{1}{(1-t)^2} \right) = (1-t)^4 \frac{t^2}{(1-t)^2} = t^2(1-t)^2\end{aligned}$$

The covariance can be obtained similarly. Assuming that $s < t$,

$$\begin{aligned}\text{Cov}(X_s, X_t) &= E(X_s X_t) = (1-s)^2(1-t)^2 E \left[\int_0^s \frac{\sqrt{2u}}{(1-u)^{3/2}} dB_u \int_0^t \frac{\sqrt{2v}}{(1-v)^{3/2}} dB_v \right] \\ &= (1-s)^2(1-t)^2 E \left[\left(\int_0^s \frac{\sqrt{2u}}{(1-u)^{3/2}} dB_u \right)^2 \right] \\ &= (1-s)^2(1-t)^2 \cdot \frac{s^2}{(1-s)^2} = s^2(1-t)^2.\end{aligned}$$

The covariance is square of that of the Brownian bridge $\text{Cov}(X_s, X_t) = s(1-t)$.

Exercise 9.6 We first derive the mean and the variance of lognormal distribution, $Y \sim \exp(\mu + \sigma Z)$, where Z is a standard normal distribution (see the same result at ([WIKIPEDIA](#))):

$$E(Y) = e^{\mu + \sigma^2/2}$$

and

$$\begin{aligned}\text{Var}(Y) &= e^{2\mu} E((e^{\sigma Z} - e^{\sigma^2/2})^2) = e^{2\mu} E(e^{2\sigma Z} - 2e^{\sigma Z + \sigma^2/2} + e^{\sigma^2}) \\ &= e^{2\mu} (e^{2\sigma^2} - 2e^{\sigma^2} + e^{\sigma^2}) = e^{2\mu + \sigma^2} (e^{\sigma^2} - 1).\end{aligned}$$

Back to the problem, for $t = kh$ and $s = (k-1)h$,

$$R_k(h) + 1 = \frac{X_t}{X_s} = \exp \left(\left(\mu - \frac{\sigma^2}{2} \right) h + \sigma(B_t - B_s) \right) = \exp \left(\left(\mu - \frac{\sigma^2}{2} \right) h + \sigma\sqrt{h}Z \right),$$

where Z is standard normal distribution. Since $R_k(h) + 1$ is a lognormal distribution with $\mu := (\mu - \sigma^2/2)h$ and $\sigma := \sigma\sqrt{h}$, we obtain the mean and the variance of $R_k(h) + 1$ as

$$\begin{aligned}E(R_k(h) + 1) &= \exp \left(\left(\mu - \frac{\sigma^2}{2} \right) h + \frac{\sigma^2}{2} h \right) = e^{\mu h} \\ \text{Var}(R_k(h) + 1) &= e^{2\mu h} (e^{\sigma^2 h} - 1).\end{aligned}$$

Therefore,

$$E(R_k(h)) = e^{\mu h} - 1 \quad \text{and} \quad \text{Var}(R_k(h)) = e^{2\mu h} (e^{\sigma^2 h} - 1)$$

and it follows that

$$\begin{aligned}\text{Var}(R_k(h)) &= (1 + E(R_k(h)))^2 (e^{\sigma^2 h} - 1) \\ \sigma^2 &= \frac{1}{h} \log \left(1 + \frac{\text{Var}(R_k(h))}{(1 + E(R_k(h)))^2} \right).\end{aligned}$$

From sample data, we can estimate the mean and the variance as

$$E(R_k(h)) = \frac{1}{n} \sum_{k=1}^n R_k(h), \quad \text{Var}(R_k(h)) = \frac{1}{n-1} \sum_{k=1}^n (R_k(h) - E(R_k(h)))^2.$$

Below are the s and σ values for various values of $E(R_k(h))$ and $\text{Stdev}(R_k(h))$:

(All numbers are in the unit of %. $h = 1/12$.)

Stdev($R_k(h)$) \rightarrow		5	10	15	20	25
$E(R_k(h))$	s	17.3	34.6	52.0	69.3	86.6
-2	σ	17.7	35.3	52.7	70.0	87.0
0		17.3	34.6	51.7	68.6	85.3
2		17.0	33.9	50.7	67.3	83.7
4		16.6	33.2	49.7	66.0	82.1
6		16.3	32.6	48.8	64.8	80.6

The values of s and σ are not significantly different unless the average return $E(R_k(h))$ is high.
